Photo-polymerisation is now a widely accepted initiation mode for the clinical hardening processes required with a wide range of biomaterials including dental adhesives and restoratives. As we discuss in detail, there is a strong relationship between the progressive phenomenon of photo-polymerisation, with attendant network formation, and shrinkage stresses and strains set up in the material and its host environment.

Disturbances in the development of the dental hard tissues of systemic origin can occur prenatally, perinatally, postnatally, during infancy or during early childhood. At birth, even the normal change from intrauterine to extrauterine life may have an adverse effect on amelogenesis and dentinogenesis as evidenced by the so called neonatal line (Figure 20.9).

Interaction with dental hard tissues The fundamental mechanism of bonding to enamel and dentine is essentially based on an exchange process in which minerals removed from the dental hard tissues are replaced by resin monomers that upon polymerization become micromechanically interlocked in the created porosities.^{6,10} Dissolution of superficial dental hard tissue is con-
